React Hooks Cheat Sheet

Mentoro study notes

useState

Holds local component state. Call the setter with a new value or an updater function when the next value depends on the previous one.

useEffect

Runs side effects after render. List every value the effect reads in the dependency array and return a cleanup function for subscriptions and timers.

useMemo and useCallback

Cache expensive calculations and stable function references. Use them when profiling shows a real cost, not by default.

useRef

Keeps a mutable value across renders without causing a re-render. Also used to reach DOM nodes.

Custom hooks

Extract reusable logic into a function whose name starts with use. Keep each hook focused on one job.
